## Scatterplot Matrix

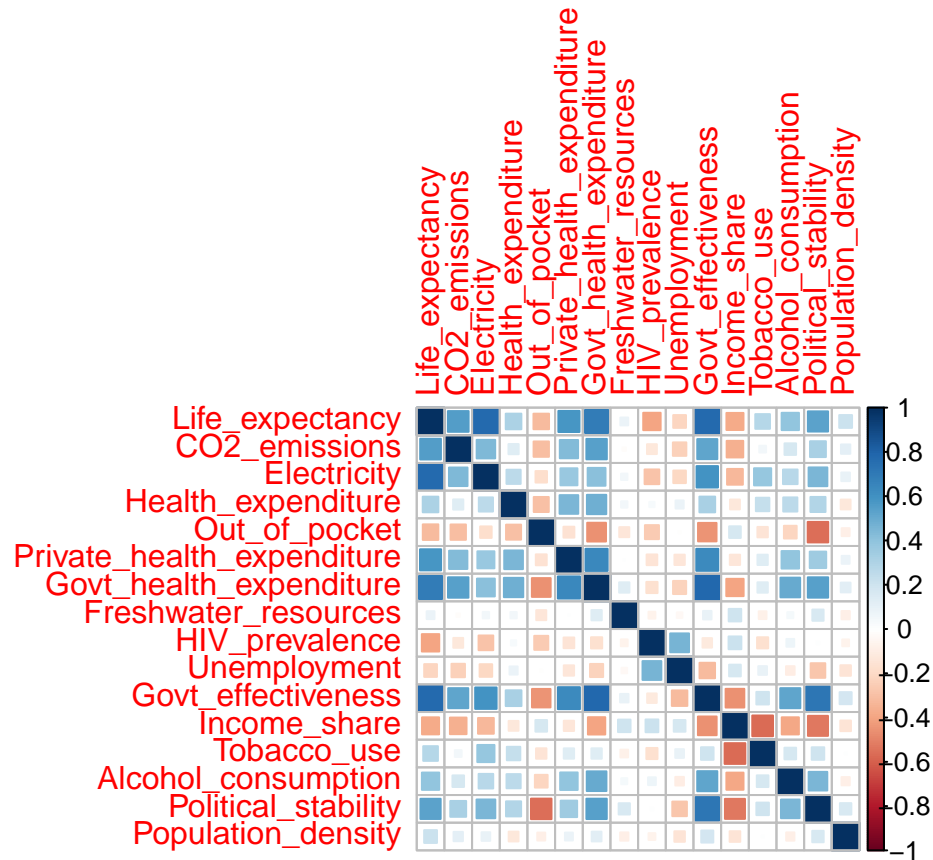

```
pairs(life_expectancy, pch = 16, lower.panel = NULL)
```

## Correlation Plot

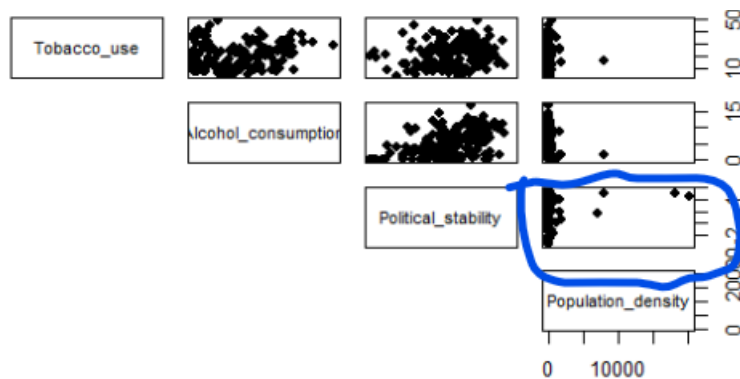

```
corrplot(corr_life_expectancy, method = "square")
```

## Likely Outliers

The following is the concept we followed when identifying outliers.

1. Find a pair of dimensions that appear to have outliers on the **Scatterplot Matrix**.

Here it appears that Population Density and Political Stability have a few outliers.

2. Find the Mahalanobis Distances for every row between those dimensions.

```
# dimension 1
dim1 <- "Private_health_expenditure" # CHANGE THIS
# dimension 2
dim2 <- "Income_share" # CHANGE THIS
# pair of dimensions
pair_dims <- c(dim1, dim2)

# all rows between the pairs of dimensions
rows_pair_dims <- life_expectancy[,pair_dims]
# centroid
centroid <- c(mean(life_expectancy[,dim1], na.rm = TRUE),
              mean(life_expectancy[,dim2], na.rm = TRUE))
# covariance matrix between dimensions
cov_pair_dims <- cov(life_expectancy[,pair_dims], use = "pairwise.complete.obs")

# mahalanobis distance for each row between these dimensions
m_dims <- mahalanobis(x = rows_pair_dims,
                     center = centroid,
                     cov = cov_pair_dims)
```

3. Compare the Mahalanobis Distances for every row to the critical value to find the outliers.

```
# our constant critical value
critical_value <- qchisq(p = 1 - 0.001, df = 2)

# find which Mahalanobis distances for every row to the critical value
outlierIndices <- which(m_dims > critical_value)
m_dims[outlierIndices]
```

```
## United States
##      49.25951
```

4. Find the correlation matrices for our pair of dimensions with and without each outlier to see if it is significant.

```
for (outlier in outlierIndices) {
  cor_with <- cor(life_expectancy[,pair_dims],
                 use = "pairwise.complete.obs")
  cor_without <- cor(life_expectancy[-outlier, pair_dims],
                   use = "pairwise.complete.obs")
  print(rownames(life_expectancy)[outlier])
  print(cor_with)
  print(cor_without)
  cat('\n')
  cat('\n')
}
```

```
## [1] "United States"
##                                     Private_health_expenditure Income_share
```

## Private_health_expenditure	1.0000000	-0.1370584
## Income_share	-0.1370584	1.0000000
##	Private_health_expenditure	Income_share
## Private_health_expenditure	1.0000000	-0.2949124
## Income_share	-0.2949124	1.0000000

---

## Find All Outliers

The following takes the idea above and does it for all pairs of dimension (however a bit redundantly).

```
outlier_matrix <- matrix(nrow = 0, ncol = 4)
colnames(outlier_matrix) <- c("Country", "dim1", "dim2", "MD")

for (i in col_names) {
  other_col_names <- col_names[col_names != i]
  for (j in other_col_names) {
    # dimension 1
    dim1 <- i
    # dimension 2
    dim2 <- j
    # pair of dimensions
    pair_dims <- c(dim1, dim2)

    # all rows between the pairs of dimensions
    rows_pair_dims <- life_expectancy[,pair_dims]
    # centroid
    centroid <- c(mean(life_expectancy[,dim1], na.rm = TRUE),
                  mean(life_expectancy[,dim2], na.rm = TRUE))
    # covariance matrix between dimensions
    cov_pair_dims <- cov(life_expectancy[,pair_dims], use = "pairwise.complete.obs")

    # mahalanobis distance for each row between these dimensions
    m_dims <- mahalanobis(x = rows_pair_dims,
                         center = centroid,
                         cov = cov_pair_dims)

    # our constant critical value
    critical_value <- qchisq(p = 1 - 0.001, df = 2)

    # find which Mahalanobis distances for every row to the critical value
    outlierIndicies <- which(m_dims > critical_value)
    m_dims[outlierIndicies]

    for (outlier in outlierIndicies) {
      country <- rownames(life_expectancy)[outlier]
      m_dist <- m_dims[outlier]
      outlier_matrix <- rbind(outlier_matrix, c(country, dim1, dim2, m_dist))
      cor_with <- cor(life_expectancy[,pair_dims],
                     use = "pairwise.complete.obs")
      cor_without <- cor(life_expectancy[-outlier, pair_dims],
                        use = "pairwise.complete.obs")
      change <- abs(cor_with[2,1] - cor_without[2,1])
    }
  }
}
```

```

        if (change > 0.3) {
            cat(sprintf("%s is an influetial outlier for the dimensions %s and %s as the correlation changes",
                        country, dim1, dim2))
            cat('\n')
            cat('\n')
        }
    }
}
}

```

We have many outliers in the following matrix, but several that are redundant. We attempted to avoid this but are unsure how to achieve this. However it is of note that none of these outliers were actually found to be influential based on the code we wrote.

outlier\_matrix
